

Please amend the Abstract with the following amended Abstract:

A ~~tray~~method of using a device which goes over and between the legs for raising and supporting human testes during ~~ultrasound~~ultrasound inspection, to assist in ~~immobilizing same to improve supporting and positioning same for~~ ultrasonic imaging, ~~adapted for use and inspection~~ when the patient is in a supine position. A pair of spaced-apart downwardly curved members are provided, having a radius of curvature approximating the curvature of a leg of a patient proximate the thigh area. Intermediate each of said curved members is a substantially flat support member, which is of a narrow width may be wider at one end than the other opposite end, to permit positioning of such support member beneath the testes of a male patient and between the legs of a patient to raise and support such testes to permit ultrasonic examination of such testes. The device may be a unitary one-piece construction, preferably of a moulded plastic, which also facilitates easy sterilization to permit re-use of the device on ~~subsequesnt patients.~~subsequent patients. The radius of curvature of each of the curved members may be greater at one end of the device than the other to better fit and more uniformly rest over the respective thigh portions of the legs of the patient.
